

# **Phosphorus in Agriculture**

## **Some current issues**

**Johnny Johnston**

**Rothamsted Research**

## **Phosphorus – the issues**

- **Phosphorus is an essential, irreplaceable nutrient in crop and animal nutrition**
- **Phosphorus lost from agriculturally managed soils to surface water bodies, *e.g.* lakes, causes the adverse effects of eutrophication**
- **Global reserves of phosphorus are limited**

## Phosphorus in crop nutrition

Roots take up phosphorus (P) as  $\text{H}_2\text{PO}_4^-$  or  $\text{HPO}_4^{2-}$  ions from the soil solution

P concentration in the soil solution in agricultural soils ranges from 0.01 to 0.3 mg P/L

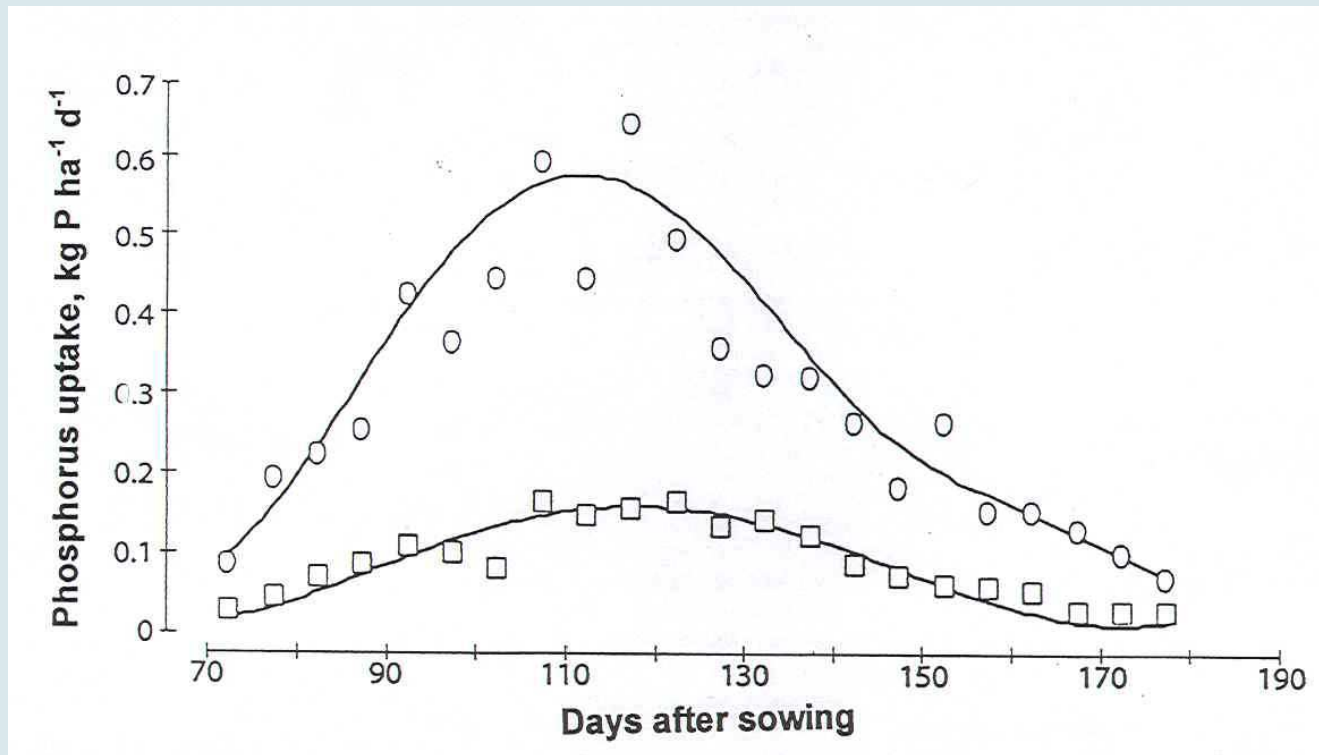

This equates to 0.3 to 3.0 kg P/ha, but roots are in contact with only about 25% of the soil solution, *i.e.* “available” P 0.08 to 0.75 kg P/ha

Daily maximum P uptake rate by spring barley with:

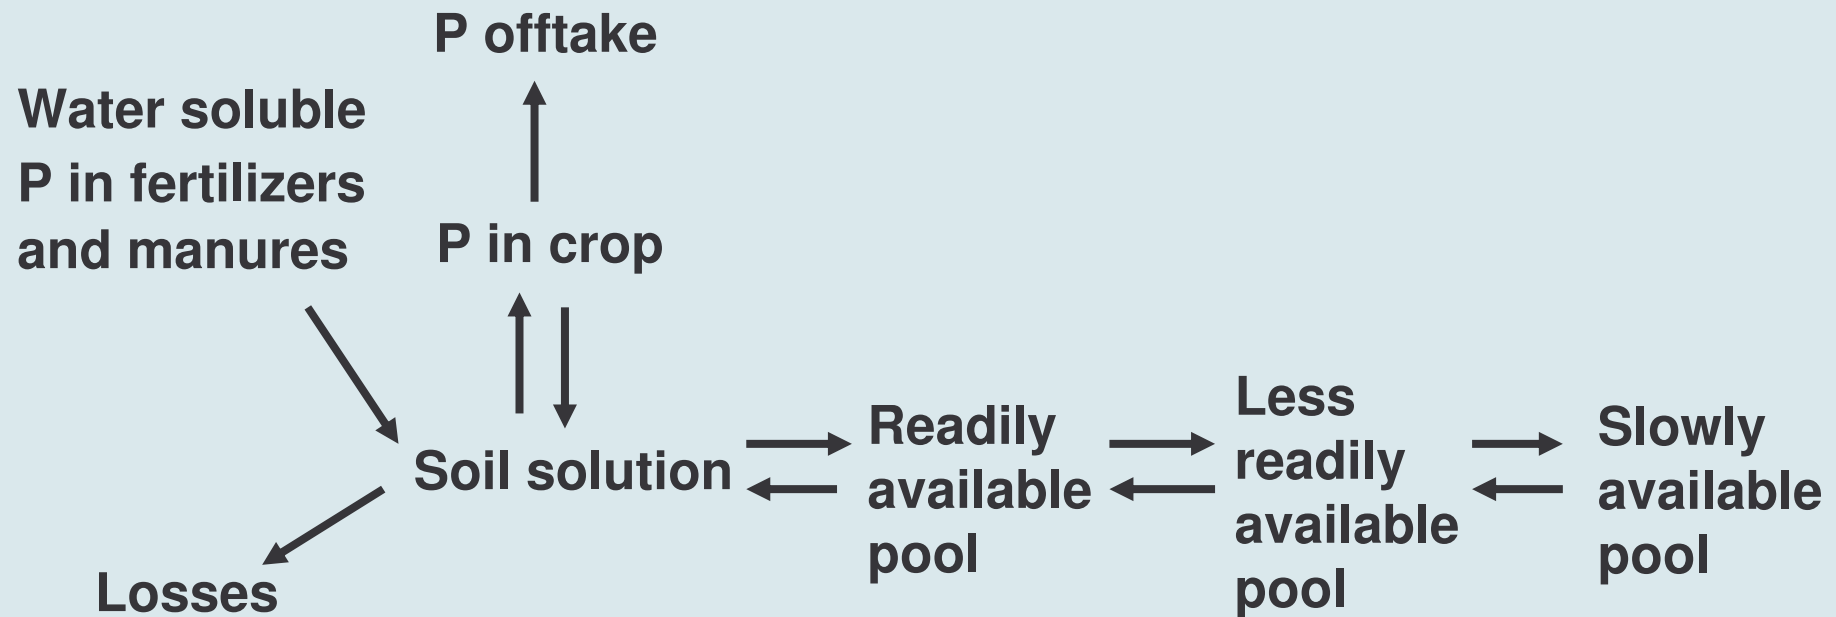

Adequate P was 0.6 kg P/ha and grain yield was 6.4 t/ha

Too little P was 0.2 kg P/ha and grain yield only 2.9 t/ha

## Determining daily phosphorus uptakes

## Current concepts of the behaviour of P in soil

Soil analysis measures P in the soil solution and the readily available pool

# Relationship between total P and Olsen P

## Relationship between total P, Olsen P and CaCl<sub>2</sub> P

|                  | Total P<br>mg/kg | Olsen P<br>mg/kg | CaCl <sub>2</sub> P<br>µg/l |

# Saxmundham: response to fresh P

## Grass response to phosphorus on soils with different levels of Olsen P

| Olsen P, mg/kg                               | 14                                  | 8   | 5   | 2   |
|--|-------------------------------------|-----|-----|-----|
| P <sub>2</sub> O <sub>5</sub> applied, kg/ha | Annual yield grass dry matter, t/ha |     |     |     |
| 0  | 8.1                                 | 6.6 | 5.1 | 3.5 |
| 50   | 9.0                                 | 8.7 | 8.3 | 7.8 |
| 100  | 9.0                                 | 9.0 | 7.5 | 8.2 |
| 150  | 9.1                                 | 8.8 | 8.5 | 8.2 |

**Is extra P required for early growth of grassland?**

**Small increases in yield are sometimes found in experiments**

**Can this be turned into saleable product?**

**If slurry is being applied is extra fertilizer P required?**

**Does fertilizer or slurry P increase the soil P level much above the critical value?**

**If required, apply slurry in spring to maintain soil at the critical level**

**Much of the P lost from soil to water comes from grassland**

## Soil analysis for P in grassland soils

Grassland usually sampled to 7.5 cm

Probably acceptable for advisory purposes but not for environmental issues

A profile of P enrichment develops in soil under permanent grassland:

| Depth, cm | Olsen P |  |
|-----------|---------|--|
| 0-0.5     | ~18     | Olsen P in bulk soil to 7.5 cm was 6.6 mg/kg |
| 0.5-1.0   | ~12     |  |
| 2         | ~7      |  |
| 7.5       | ~5      |  |
| 12.5      | ~4      |  |
| 17.5      | ~3      |  |

Data from IGER North Wyke experiments

## **Factors affecting the critical level of Olsen P**

- **Soil analysis carried out on soil <2mm.**

**Therefore the amount of soil <2mm is important;  
this is affected by soil depth and stoniness.**

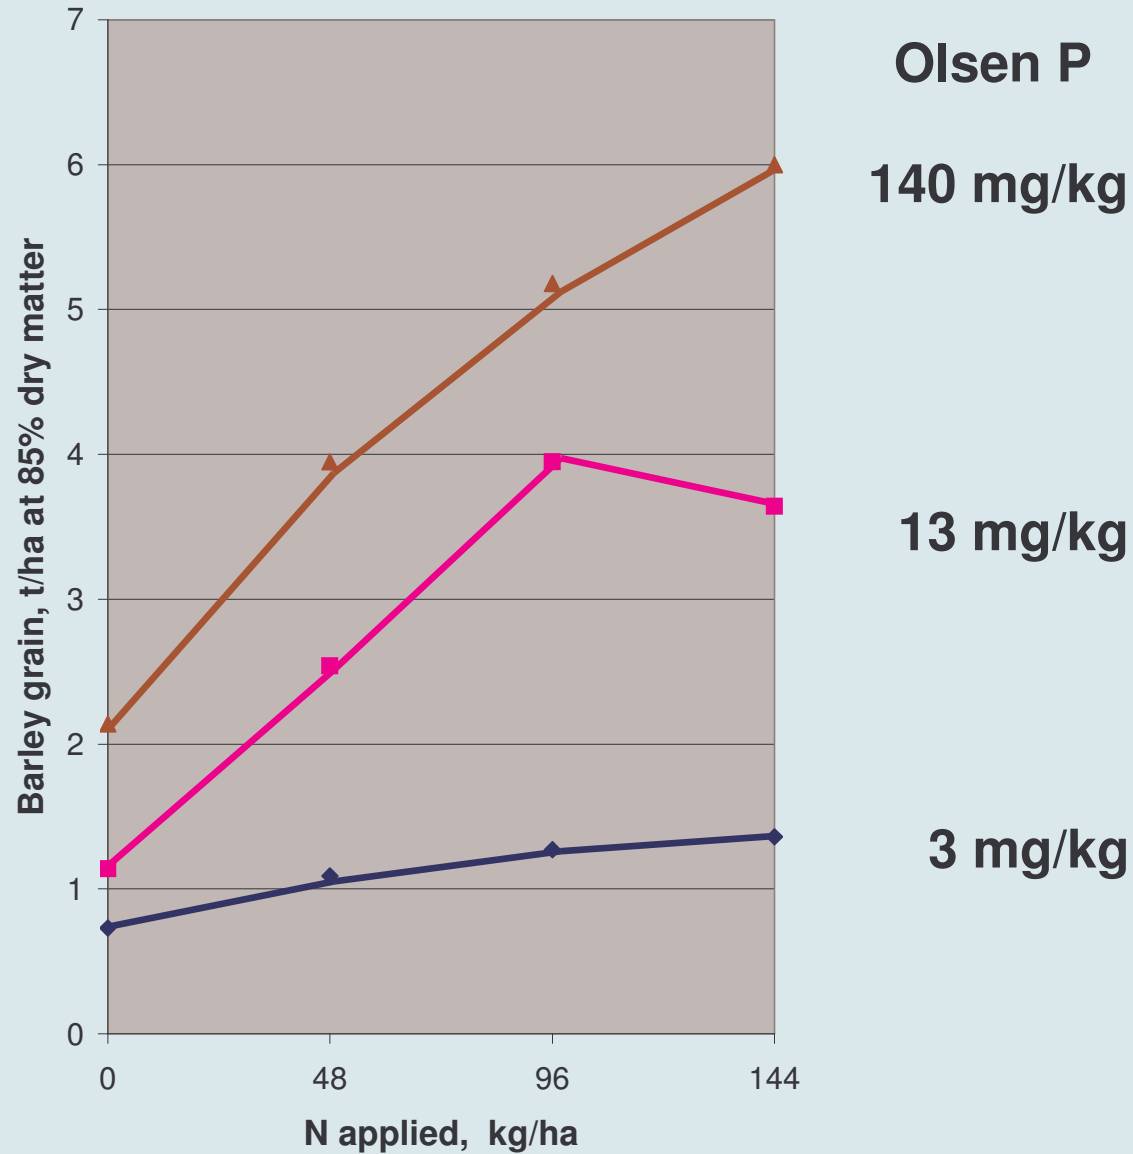

- **How much soil <2mm is explored by plant roots?**

**This is related to soil structure and  
soil organic matter**

## Effect of soil organic matter on relationship between yield and Olsen P

|   | SOM<br>% | Yield<br>t/ha<br>(asymptote) | Olsen P<br>mg/kg<br>(at 95%) | % variance<br>accounted for |
|---|----------|------------------------------|------------------------------|-----------------------------|
| Spring barley<br>grain                  | 1.5      | 4.4                          | 45                           | 46                          |

# Saxmundham: changes in Olsen P with treatment and time

No fresh added after 1968

18 kg/ha/yr 1969-77  
26 kg/ha/yr 1978-83

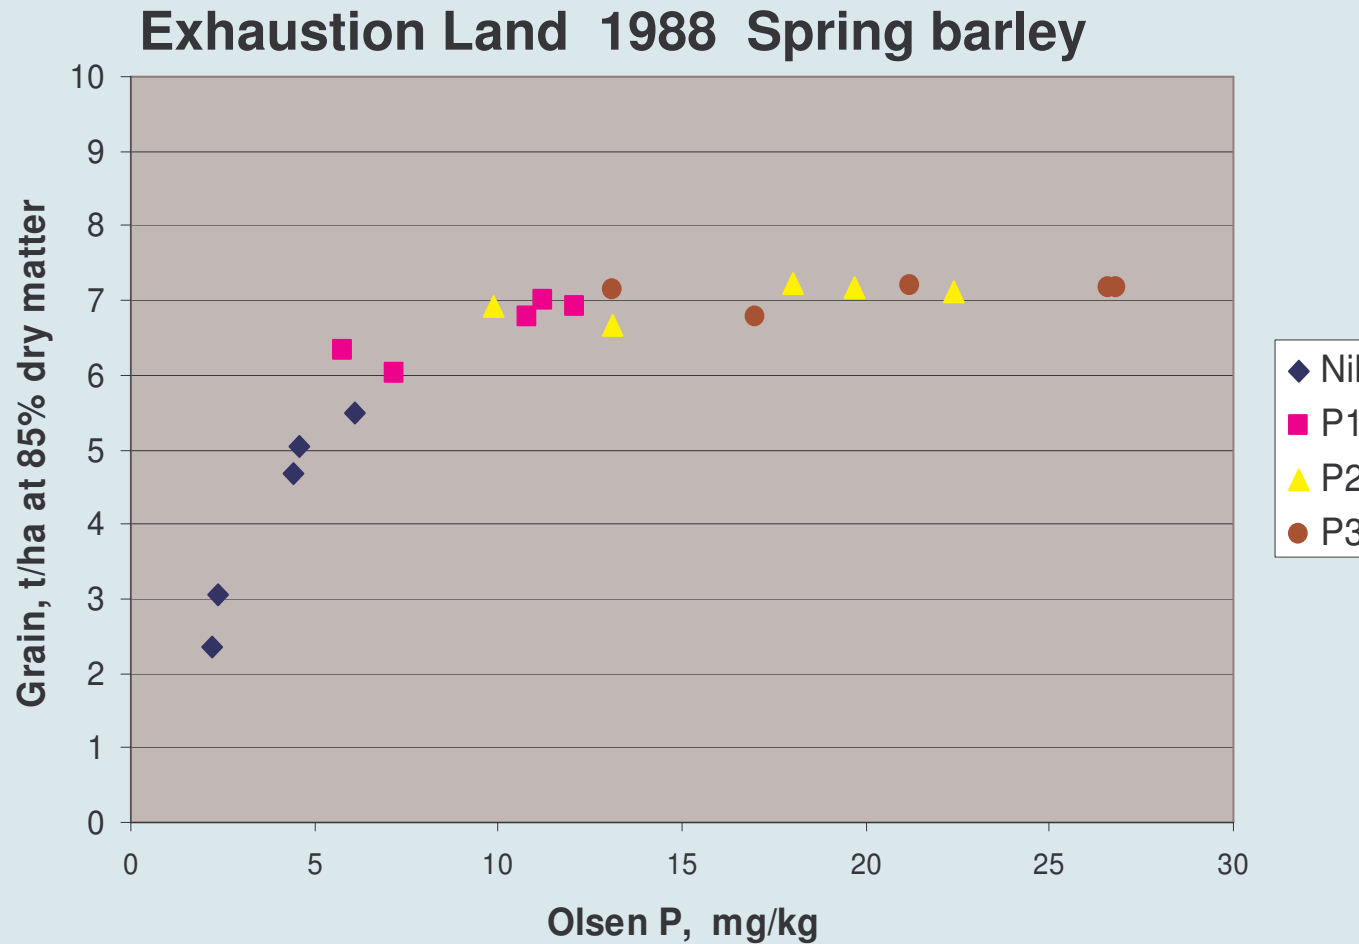

## Saxmundham: decline in Olsen P, unified decay curve

**No fertilizer P added after 1968**

**“Half-life” of about 10 years**

On some soils it is possible to increase available P within a few years by applying much P so that yields are not limited; it will take much longer on “difficult” soils

P added annually since 1986; P1, P2, P3: 100, 200, 300 P<sub>2</sub>O<sub>5</sub>/ha

## **Making a judgement about applying phosphorus**

**Soils below the critical value – there is a yield and thus a financial loss to the farmer**

**Apply P to increase soil P to the critical value**

**Soils above the critical value**

**Financial cost in applying P that will not increase yield**

**Increased risk of P loss to water from soils excessively enriched with P**

**Soils at the critical value**

**Apply P to maintain the critical value, maintenance applications.**

**Check that this level is being maintained by sampling and analysing soil every 4/5 years**

**Soil sample same time each year, same depth, minimum 16 cores**

## Transport of P from soil to water

In eroded soil

By movement through soil into drainage ditches and rivers

Incidental losses from surface applied slurries and fertilizers when rainfall causes surface run-off

## Phosphorus transport from soil to water

The lower limiting P concentration for a lake to be considered eutrophic is 35  $\mu\text{g P/L}$  and hypereutrophic is 100  $\mu\text{g P/L}$

The amount of water-soluble P in drainage need to achieve these concentrations is very small.

| Concentration of P<br>in water | Drainage, mm/ha/year |      |      |      |
|--------------------------------|----------------------|------|------|------|
|                                | 100                  | 250  | 500  | 1000 |
| 35 $\mu\text{g P/L}$           | 0.03                 | 0.09 | 0.18 | 0.35 |
| 100 $\mu\text{g P/L}$          | 0.10                 | 0.24 | 0.49 | 1.00 |

# The bioavailability of phosphorus transported to water

Bioavailable P is estimated by the method of analysis

The solution may or may not be filtered and may or may not be digested, P is determined by the molybdenum blue method

The filter is 0.45  $\mu\text{m}$  to separate “dissolved” from “particulate” P

## 1. Analysis of untreated solution

(i)  $\text{RP}_{<0.45}$  reactive P in filtered solution

(ii)  $\text{RP}_{\text{unf}}$  reactive P in unfiltered solution

## 2. Analysis of digested solution

(i)  $\text{TP}_{<0.45}$  total P in the filtered digest

(ii)  $\text{TP}_{\text{unf}}$  total P in the filtered digest

# **Loss of phosphorus from agriculturally managed soils**

**P has to be transported in water moving by two pathways**

- 1. Water flowing over the soil surface (overland flow) when rainfall exceeds the capacity of the soil to accept the amount of water**
- 2. Water draining down through the soil, subsurface runoff, ground water runoff. Water can move by:**

**preferential, bypass, macropore flow, through continuous pores or fissures, root channels and animal burrows resulting in rapid water movement, usually on heavy textured soils**  
**piston flow, uniform downward movement, usually in light textured, sandy soils**

**P transported down through the soil profile can be retained at depth if there are suitable sites for its adsorption**

**In certain situations soil and the P it contains can be lost by wind erosion**

## **Issues related to phosphorus loss from soil to water**

**The amounts of P lost are very variable both in space and time within a river catchment area**

**Largest losses occur in hilly terrain with large amounts of rainfall, and from inappropriate applications of slurry**

**If slurry is applied to arable land, *e.g.* to maize fields, then the soil should be loosened first or the slurry incorporated as soon as possible**

**Great care should be taken near water courses when applying slurry or fertilizers**

## **Rainfall and its relation to phosphorus loss from soil**

- 1. Intense rainfall detaches soil particles, together with the P they contain, from the main body of soil and as the excess water moves over the soil surface the entrained particles are carried to ditches, streams, rivers and lakes.  
*i.e.* soil erosion usually from land without vegetative cover,  
*e.g.* poached areas**
- 2. Incidental P transfers in overland flow when large amounts of manure or fertilizer are applied and heavy rain follows soon after application**

## **Minimising P loss**

### **By soil erosion**

**Maintain the vegetative cover, don't let the topsoil become over enriched with P, especially the top 2 cm of grassland**

### **By incidental P transfers**

**Can be from both fertilizers and manures**

**Do not apply either to water logged soils during periods of heavy rain or when heavy rain is expected**

**On mainly grassland farms where maize is taken as an arable crop either cultivate the soil prior to or immediately after slurry application**

**There is greater opportunity to apply fertilizers at the most appropriate time**

# Relationship between yield, Olsen P and total P losses in drainage

## **Sources of phosphorus inputs for agricultural soils**

**Fertilizers like TSP– stated solubility in water as a % of NAC soluble P, currently 93% for TSP. But what about fertilizers with less water soluble P?**

**Organic manures – immediate availability of the P they contain is given in RB 209**

**For soils at the critical level immediate availability is less important than whether a maintenance application will maintain the critical value for Olsen P**

**For FYM and slurry the answer is probably yes**

**But for fertilizers other than TSP etc? I don't know**

## **Alternative phosphorus fertilizers**

**For soils with a range of pH**

**Nitrophosphates with 80% ws P as good as TSP in experiments**

**Dicalcium phosphate (not water soluble) as good as SSP**

**On neutral/calcareous soils – reactive rock phosphate ineffective even after 30 years in one Rothamsted experiment where there was no increase in Olsen P and the soil was neutral in pH**

**On acid soils rock phosphate can give good yields**

**Surface few cm of grassland, even on calcareous soils, becomes acid so that rock phosphates can be used but they must be “reactive” and finely ground**
